Documentation of my Large-Language Model Trading Advisor

Description of Project:

- I wanted to find a way to integrate LLM into my trading workflow, especially in the part of the process in which I am trying to figure out when is the right signal to buy and I would like to reduce the biases that form due to human emotions.
- The project is a foundational level of difficulty, in order to test it out on base cases first, so I decided that the model will only advise me on buy-side and it will only check ETFs. There is no consideration of sell-side, options, futures, crypto or other types of contracts.

Software Flow:

Libraries used: Future improvements:

- NumPy
- Pandas
- yfinance
- dataclass
- dotenv
- google
- genai
- math
- Improve the prompt/set of instructions that I provide the LLM by making it more targetted towards using certain mathematical models.
- Getting the LLM to suggest me other ETFs that I could buy besides just my watchlist.
- Getting the LLM to suggest me the news and event dates that I should watch out for that cause changes in stock prices.
- Start looking into buying of futures by updating software with futures' pricing models
